## 1 Problem 1

## 1.1 a)

Consider the polynomial  $P(x) = x^5 + x^2 + 1 \in \mathbb{F}_2[x]$  with coefficients in the finite field  $\mathbb{F}_2$ . You are asked to check if this polynomial is a primitive polynomial. Describe an approach to test if P(x) is primitive. [Refer to the lecture slides on primitive polynomials and LFSRs]. Write a program in Singular to test if P(x) is a primitive polynomial.

#### 1.1.1 Describing the approach

Testing whether or not a P(x) is a primitive requires a proof of the properties of the primitive polynomial. To do this, we can show that  $P(x) \in \mathbb{F}_2[x]$  has a degree such that the smallest integer n that allows P(x) to divide  $x^n + 1$  is  $2^k - 1$ . So for our case, we would like to show that  $n = 2^5 - 1 = 31$ . We can do this with the code we wrote in HW 1 for checking the gcd of the target, or just perform the exhaustive calculation showing the gcd being 1 for all except our target.

Additionally, we could show that the primitive polynomial is capable of generating all exponents? reword this

## 1.1.2 Program output

```

```

#### 1.2 b)

Design a Type-I or Type-II linear feedback shift register (LFSR) using the above P(x) as its characteristic polynomial. Starting with a non-0 seed value (reset values in the LFSR flip-flops should be non-zero), does your LFSR produce a maximal-length pseudo-random sequence? Show the 5-bit sequences produced by your LFSR. You can do this in Verilog (preferable), or Singular, or any other software.

#### 1.2.1 LFSR Design

Design of the LFSR uses a DFF module and a 5-bit collection made of 5 DFFs in a row. The bits produce a maximal sequence as can be seen in the verilog output below. There is a copy of the testbench and LFSR.v as well as the DFF.v in the homework files:

#### 1.2.2 Showing the maximal-length pseudo-random output

Below we can see that the LFSR cylces through all combinations of  $2^5$  before repeating, as expected. Here is a block of it running in emacs after compilation

## 1.3 c)

Refer to Fig. 1. Using a 5-bit plaintext P, and a seed (reset) value for your LFSR, demonstrate that your LFSR can indeed be used as a stream cipher to encrypt (compute C) and decrypt (get back P) one-bit at a time. Once again, it is convenient to demonstrate this using Verilog coding and simulation.

## 1.3.1 Stream Cypher Results $P \Rightarrow C \Rightarrow P$

The results of the system above, working is shown below. This was accomplished using the same LFSR testbench.

#### 2 Problem 2

Mastrovito Multiplier Design - In this question, you will design a digital logic circuit of a Mastrovito multiplier, i.e. the one that computes  $A \cdot B \pmod{P(x)}$ , as given in my slides. You will implement your design in Verilog, and demonstrate – by means of exhaustive simulation – that modulo-multiplication is being performed. Proceed as follows:

#### 2.1 a)

We will use the finite field  $\mathbb{F}_8 \equiv \mathbb{F}_2[x] \pmod{P(x)} = x^3 + x^2 + 1$  with  $P(\alpha) = 0$ . Denote the degree of P(x) as k; of course, here k = 3.

#### 2.2 b)

Design a k=3 bit finite field Mastrovito multiplier that takes  $A=\{a2,a1,a0\}$  and  $B=\{b2,b1,b0\}$  as 3-bit inputs, and produces  $Z=\{z2,z1,z0\}$  as a 3-bit output. Note that we will have:

$$A = a_0 + a_1\alpha + a_2\alpha^2$$
$$B = b_0 + b_1\alpha + b_2\alpha^2$$
$$Z = z_0 + z_1\alpha + z_2\alpha^2$$

Such that  $Z = A \cdot B \pmod{P(\alpha)}$ .

## 2.3 c)

Give Boolean equations (or polynomial equations (mod 2)) of the outputs in terms of inputs, and draw the gate-level schematic. We covered Mastrovito multiplier design in the class when we studied GF circuits. It is given in the slides and in my Book Chapter that I've uploaded on Canvas.

$$s_0 = a_0 \cdot b_0$$

$$s_1 = a_1 \cdot b_0 + a_0 \cdot b_1$$

$$s_2 = a_2 \cdot b_0 + a_1 \cdot b_1 + a_0 \cdot b_2$$

$$s_3 = a_2 \cdot b_1 + a_1 \cdot b_2$$

$$s_4 = a_2 \cdot b_2$$

The result is larger than our bit length so we must perform modulo reduction on the parts that go beyond our length.  $s_3$  and  $s_4$  must be reduced.

```
printing A^0 = 1
printing A^1 = (A)
printing A^2 = (A2)
printing A^3 = (A2+1)
printing A^4 = (A2+A+1)
printing A^5 = (A+1)
printing A^6 = (A2+A)
printing A^7 = 1
Auf Wiedersehen.
```

Given the reduction we can see above, we will be replacing  $\alpha^3$  and  $\alpha^4$  with  $\alpha^2 + 1$  and  $\alpha^2 + \alpha + 1$  respectively.

$$\alpha^{3} = \alpha^{2} + 1$$

$$\alpha^{4} = \alpha^{2} + \alpha + 1$$

$$S = s_{0} + s_{1}\alpha + s_{2}\alpha^{2} + s_{3}\alpha^{3} + s_{4}\alpha^{4}$$

$$S = s_{0} + s_{1}\alpha + s_{2}\alpha^{2} + s_{3}(\alpha^{2} + 1) + s_{4}(\alpha^{2} + \alpha + 1)$$

$$S = (s_{0} + s_{3} + s_{4}) + (s_{1} + s_{4})\alpha + (s_{2} + s_{3} + s_{4})\alpha^{2}$$

$$Z_{0} = S_{0} = s_{0} + s_{3} + s_{4}$$

$$Z_{1} = S_{1} = s_{1} + s_{4}$$

$$Z_{2} = S_{2} = s_{2} + s_{3} + s_{4}$$

### 2.4 d)

Implement the design in Verilog (as a GFMult(A, B, Z) module) and demonstrate its correctness via exhaustive simulation.

Above we can see the exhaustive printed results of the multiplier. As an example, the final row we see gives

This corresponds of the following:

$$111 \cdot 111 = 010$$
$$(\alpha^2 + \alpha + 1) \cdot (\alpha^2 + \alpha + 1) = \alpha$$

The expression above can be shown to reduce to  $\alpha$  by replacing  $\alpha^3$  with  $\alpha^2+1$ , and  $\alpha^4$  with  $\alpha^2+\alpha+1$ -the rest will reduce in a similar way giving us the expected results.

$$(\alpha^{2} + \alpha + 1) \cdot (\alpha^{2} + \alpha + 1) = \alpha$$

$$(\alpha^{2} + \alpha + 1) \cdot \alpha^{2} + (\alpha^{2} + \alpha + 1) \cdot \alpha + (\alpha^{2} + \alpha + 1) =$$

$$(\alpha^{4} + \alpha^{3} + \alpha^{2}) + (\alpha^{3} + \alpha^{2} + \alpha) + (\alpha^{2} + \alpha + 1) =$$

$$\alpha^{4} + 2\alpha^{3} + 3\alpha^{2} + 2\alpha + 1 =$$

$$\alpha^{4} + 2\alpha^{3} + 3\alpha^{2} + 2\alpha + 1 =$$

$$\alpha^{4} + 3\alpha^{2} + 1 = \alpha^{2} + \alpha + 1 + 3\alpha^{2} + 1$$

$$= 4\alpha^{2} + \alpha + 2$$

$$= \alpha$$

#### 2.5 e)

Using any Verilog synthesis and simulation tool, synthesize the circuit into a netlist.

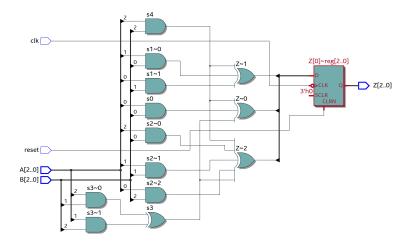

Figure 1: multiplier netlist view

#### 2.6 f)

Using any of the Cyclone V devices, synthesize the circuit for the selected FPGA architecture.

• Done.

### 2.7 g)

Note down the area and the delay of the circuit. The synthesis tools will give this information in the synthesis report. Area could be the actual area, or in terms of the number of gates, or in terms of the number of LUTs of the FPGA. Delay could be the actual delay, or the topological depth of the circuit.

• Bit fuzzy on where this data is. REVIEW THIS AND UPDATE BEFORE TURNIN

## 3 Problem 3

Now you will design a Montgomery multiplier for the same finite field as given above:

$$\mathbb{F}_8 \equiv \mathbb{F}_2[x](modP(x) = x^3 + x^2 + 1)$$
 with  $P(\alpha) = 0$ .

#### 3.1 a)

First, you will design a Montgomery Block  $MM(A, B, \alpha^{-k}) = A \cdot B \cdot \alpha^{-k} (mod P(\alpha))$ , as shown in the slides as well as in my book chapter.

#### 3.2 b)

Then, you will put 4 of these blocks together to design a multiplication circuit that computes  $G = A \cdot B(modP(x))$ .

#### 3.3 c)

For the design of a MM block, you should use Algorithm 1 in my textbook chapter, unroll the loop k-times and design a *combinational circuit*.

#### 3.4 d)

Design the circuit in Verilog.

#### 3.5 e)

Simulate the multiplier exhaustively to demonstrate its correct operation.

#### 3.6 f

Synthesize the circuit, report the area and delay statistics, comparing it with the Mastrovito design.

## 4 Problem 4

If P is a primitive polynomial, then  $P^*$  will be as well. Therefore if  $\alpha$  is a root of P,  $\alpha^{-1}$  will be a root of  $P^*$ .

### 4.1 Showing the process

$$P(\alpha) = 0$$

$$P(x) = a_0 x^k + a_1 x^{k-1} + a_2 x^{k-2} + \dots + a_{k-1} x + a_k$$

$$P^* \left(\frac{1}{x}\right) = b_0 x^k + b_1 x^{k-1} + b_2 x^{k-2} + \dots + b_{k-1} x + b_k$$

$$P^* \left(\frac{1}{x}\right) = b_0 \frac{1}{x}^k + b_1 \frac{1}{x}^{k-1} + b_2 \frac{1}{x}^{k-2} + \dots + b_{k-1} \frac{1}{x} + b_k$$

$$= b_0 x^{-k} + b_1 x^{-k+1} + b_2 x^{-k+2} + \dots + b_{k-1} x^{-1} + b_k$$

normalizing the expression by  $x^k$  should not change the overall expression since  $x^k = 1$  by the cyclic nature of the root.

$$= x^{k} \cdot (b_{0}x^{-k} + b_{1}x^{-k+1} + b_{2}x^{-k+2} + \dots + b_{k-1}x^{-1} + b_{k})$$
  
=  $b_{0} + b_{1}x + b_{2}x^{2} + \dots + b_{k-1}x^{k-1} + b_{k}x^{k}$ 

Now we can see that the expression is equal to the first with the coefficients reversed.
